Effects Models
Norm Matloff
University of
California at
    Davis
- Given, a mixed-effects model.
```

## Overview

- Given, a mixed-effects model.
- Change to a fully random model, treating fixed factors as samples from populations.

## Overview

- Given, a mixed-effects model.
- Change to a fully random model, treating fixed factors as samples from populations.
- Note that get (essentially) the same variances, thus the same Method of Moments estimators.

## Overview

- Given, a mixed-effects model.
- Change to a fully random model, treating fixed factors as samples from populations.
- Note that get (essentially) the same variances, thus the same Method of Moments estimators.
- Consider the former $n_{i}$ to be random, i.e. $N_{i}$, with their own effects worth studying.

## Overview

- Given, a mixed-effects model.
- Change to a fully random model, treating fixed factors as samples from populations.
- Note that get (essentially) the same variances, thus the same Method of Moments estimators.
- Consider the former $n_{i}$ to be random, i.e. $N_{i}$, with their own effects worth studying. (In 2-factor models, $N_{i}$ are row counts, and have column counts $M_{i}$. Etc.)
New Computational

## Simple Example

- Classic 1-random-factor model,

$$
\begin{equation*}
Y_{i j}=\mu+\alpha_{i}+\epsilon_{i j}, \quad i=1, \ldots, r, j=1, \ldots, n_{i} \tag{1}
\end{equation*}
$$

$$
\begin{gather*}
\begin{array}{c}
\text { New Compu- } \\
\text { tational } \\
\text { Approaches to } \\
\text { Large/ Com- } \\
\text { plex Mixed }
\end{array} \\
\text { Effects Models }
\end{gather*} \quad \text { Simple Example }
$$

- Not considered "mixed," but it really is,

## Simple Example

- Classic 1-random-factor model,

$$
\begin{equation*}
Y_{i j}=\mu+\alpha_{i}+\epsilon_{i j}, \quad i=1, \ldots, r, j=1, \ldots, n_{i} \tag{1}
\end{equation*}
$$

- Not considered "mixed," but it really is, since the $n_{i}$ are considered constants.

## Simple Example

- Classic 1-random-factor model,

$$
\begin{equation*}
Y_{i j}=\mu+\alpha_{i}+\epsilon_{i j}, i=1, \ldots, r, j=1, \ldots, n_{i} \tag{1}
\end{equation*}
$$

- Not considered "mixed," but it really is, since the $n_{i}$ are considered constants.
- But change $n_{i}$ to $N_{i}$, assume latter are i.i.d.

## Simple Example

- Classic 1-random-factor model,

$$
\begin{equation*}
Y_{i j}=\mu+\alpha_{i}+\epsilon_{i j}, \quad i=1, \ldots, r, j=1, \ldots, n_{i} \tag{1}
\end{equation*}
$$

- Not considered "mixed," but it really is, since the $n_{i}$ are considered constants.
- But change $n_{i}$ to $N_{i}$, assume latter are i.i.d.
- Why do this?

## Simple Example

- Classic 1-random-factor model,

$$
\begin{equation*}
Y_{i j}=\mu+\alpha_{i}+\epsilon_{i j}, \quad i=1, \ldots, r, j=1, \ldots, n_{i} \tag{1}
\end{equation*}
$$

- Not considered "mixed," but it really is, since the $n_{i}$ are considered constants.
- But change $n_{i}$ to $N_{i}$, assume latter are i.i.d.
- Why do this?
- Makes quantities like $Y_{i .}=\sum_{j=1}^{N_{i}} Y_{i j} / N_{i}$ i.i.d., thus easy algebra.

## Simple Example

- Classic 1-random-factor model,

$$
\begin{equation*}
Y_{i j}=\mu+\alpha_{i}+\epsilon_{i j}, i=1, \ldots, r, j=1, \ldots, n_{i} \tag{1}
\end{equation*}
$$

- Not considered "mixed," but it really is, since the $n_{i}$ are considered constants.
- But change $n_{i}$ to $N_{i}$, assume latter are i.i.d.
- Why do this?
- Makes quantities like $Y_{i .}=\sum_{j=1}^{N_{i}} Y_{i j} / N_{i}$ i.i.d., thus easy algebra.
- Enables statistical analysis of $N$ !

## Streamlining the Algebra

Consider again the simple model
JSM 2016

$$
\begin{equation*}
Y_{i j}=\mu+\alpha_{i}+\epsilon_{i j}, \quad i=1, \ldots, r, j=1, \ldots, N_{i} \tag{3}
\end{equation*}
$$

New Computational Approaches to Large/Complex Mixed Effects Models Norm Matloff University of California at Davis

JSM 2016

## Streamlining the Algebra

Consider again the simple model

$$
\begin{equation*}
Y_{i j}=\mu+\alpha_{i}+\epsilon_{i j}, \quad i=1, \ldots, r, j=1, \ldots, N_{i} \tag{3}
\end{equation*}
$$

- We want to estimate $\sigma_{\alpha}^{2}$, and possibly $\sigma_{\epsilon}^{2}$.

## Streamlining the Algebra

Consider again the simple model

$$
\begin{equation*}
Y_{i j}=\mu+\alpha_{i}+\epsilon_{i j}, \quad i=1, \ldots, r, j=1, \ldots, N_{i} \tag{3}
\end{equation*}
$$

- We want to estimate $\sigma_{\alpha}^{2}$, and possibly $\sigma_{\epsilon}^{2}$.
- The Method of Moments approach is safer (no normality assumptions).

## Streamlining the Algebra

Consider again the simple model

$$
\begin{equation*}
Y_{i j}=\mu+\alpha_{i}+\epsilon_{i j}, \quad i=1, \ldots, r, j=1, \ldots, N_{i} \tag{3}
\end{equation*}
$$

- We want to estimate $\sigma_{\alpha}^{2}$, and possibly $\sigma_{\epsilon}^{2}$.
- The Method of Moments approach is safer (no normality assumptions). But deriving the equations is messy.

## Streamlining the Algebra

Consider again the simple model

$$
\begin{equation*}
Y_{i j}=\mu+\alpha_{i}+\epsilon_{i j}, i=1, \ldots, r, j=1, \ldots, N_{i} \tag{3}
\end{equation*}
$$

- We want to estimate $\sigma_{\alpha}^{2}$, and possibly $\sigma_{\epsilon}^{2}$.
- The Method of Moments approach is safer (no normality assumptions). But deriving the equations is messy.
- Once we go to two-factor models, add regressors etc., things get even messier, FAST.

\section*{Back to the Simple Example}

Write \(Y=\mu+\alpha+\epsilon\) and, motivated by defining
\[
\begin{equation*}
S_{i}=\sum_{j=1}^{N_{i}} Y_{i j} \approx N \mu+N \alpha \tag{5}
\end{equation*}
\]
also write \(S=N \mu+N \alpha+\epsilon_{1}+\ldots+\epsilon_{N}\)

\section*{Back to the Simple Example}

Write \(Y=\mu+\alpha+\epsilon\) and, motivated by defining
\[
\begin{equation*}
S_{i}=\sum_{j=1}^{N_{i}} Y_{i j} \approx N \mu+N \alpha \tag{5}
\end{equation*}
\]
also write \(S=N \mu+N \alpha+\epsilon_{1}+\ldots+\epsilon_{N}\)

Then apply the "Pythagorean Theorem" with \(W=S, U=N\),

\section*{Back to the Simple Example}

Write \(Y=\mu+\alpha+\epsilon\) and, motivated by defining
\[
\begin{equation*}
S_{i}=\sum_{j=1}^{N_{i}} Y_{i j} \approx N \mu+N \alpha \tag{5}
\end{equation*}
\]
also write \(S=N \mu+N \alpha+\epsilon_{1}+\ldots+\epsilon_{N}\)

Then apply the "Pythagorean Theorem" with \(W=S, U=N\), using facts like
\[
\begin{equation*}
\operatorname{Var}(S \mid N)=N^{2} \operatorname{Var}(\alpha)+N \sigma_{\epsilon}^{2} \tag{6}
\end{equation*}
\]

\section*{Back to the Simple Example}

Write \(Y=\mu+\alpha+\epsilon\) and, motivated by defining
\[
\begin{equation*}
S_{i}=\sum_{j=1}^{N_{i}} Y_{i j} \approx N \mu+N \alpha \tag{5}
\end{equation*}
\]
also write \(S=N \mu+N \alpha+\epsilon_{1}+\ldots+\epsilon_{N}\)

Then apply the "Pythagorean Theorem" with \(W=S, U=N\), using facts like
\[
\begin{equation*}
\operatorname{Var}(S \mid N)=N^{2} \operatorname{Var}(\alpha)+N \sigma_{\epsilon}^{2} \tag{6}
\end{equation*}
\]

Finally, replace pop. quantities by sample analogs, and solve.
New Computational

\section*{Almost-Simple Example}

\section*{Almost-Simple Example}

\section*{Let's add a covariate:}
\[
\begin{gather*}
Y=\beta_{0}+X \beta_{1}+\alpha+\epsilon  \tag{8}\\
S=N\left(\beta_{0}+X \beta_{1}+\alpha\right)+\epsilon_{1}+\ldots+\epsilon_{N} \tag{9}
\end{gather*}
\]
and the matrix equation
\[
\begin{equation*}
\mathbb{Y}=\mathbb{B}_{0}+\mathbb{X} \beta_{1}+\mathbb{A}+\mathbb{G} \tag{10}
\end{equation*}
\]

This is already getting messy even in this form, but much better than the standard way, with all the messy sums.

\title{
What If the Fixed Effects Really Are Fixed?
}
- E.g. 5 different drugs for hypertension.
```

## What If the Fixed Effects Really

 Are Fixed?Norm Matloff University of California at Davis

- E.g. 5 different drugs for hypertension.
- May not feel comfortable with these being sample from a "population" of drugs.

## What If the Fixed Effects Really

## Are Fixed?

Norm Matloff University of California at Davis

- E.g. 5 different drugs for hypertension.
- May not feel comfortable with these being sample from a "population" of drugs.
- But can treat each observation's drug as a sample from the 5 , making the $N_{i}$ random.

## What If the Fixed Effects Really

## Are Fixed?

Norm Matloff

- E.g. 5 different drugs for hypertension.
- May not feel comfortable with these being sample from a "population" of drugs.
- But can treat each observation's drug as a sample from the 5 , making the $N_{i}$ random.
- Can show that we still get the same answer!
- E.g. 5 different drugs for hypertension.
- May not feel comfortable with these being sample from a "population" of drugs.
- But can treat each observation's drug as a sample from the 5 , making the $N_{i}$ random.
- Can show that we still get the same answer!
- Hence my charactizeration of the method as an algebraic computational device.
